29th of September, 2004

## 1 Introduction

SR (synchronizing resources)[1] is a PASCAL – style language enhanced with constructs for concurrent programming developed at the University of Arizona in the late 1980s[2]. MPD (presented in Gregory Andrews’ book about Foundations of Multithreaded, Parallel, and Distributed Programming[3]) is its successor, providing the same language primitives with a different syntax.

The run-time system (in theory, identical) of both languages provides the illusion of a multiprocessor machine on a single single- or multi- CPU Unix-like system or a (local area) network of Unix-like machines.

Chair V of the Computer Science Department of the University of Bonn is operating a laboratory for a practical course in parallel programming consisting of computing nodes running NetBSD/arm, normally used via PVM, MPI etc.

We are considering to offer SR and MPD for this, too. As the original language distributions are only targeted at a few commercial Unix systems, some porting effort is needed, outlined in the SR porting guide[4].

The integrated POSIX threads support of NetBSD-2.0 should allow us to use library primitives provided for NetBSD’s pthread system to implement the primitives needed by the SR run-time system, thus implementing 13 target CPUs at once and automatically making use of SMP on VAX, Alpha, PowerPC, Sparc, 32-bit Intel and 64 bit AMD CPUs.

This paper describes work in progress.

## 2 Generic Porting Problems

Given the age of the software and the gradual development of the C language and the operating system environments available, some adaptation is to be expected. Fortunately, the latest distribution of SR (version 2.3.2) has already been ported to two relatively modern Unix-like environments (Solaris 2.2 and Linux), so the necessary changes turned out to be confined to a one area:

`gcc 3`, the system compiler of NetBSD-2.0, doesn’t provide old `<varargs.h>` variable argument functions anymore, so those had to be converted to `<stdarg.h>` syntax. Also, none of those functions had fixed arguments. Most of the functions had a first logical parameter `char *locn` which could be changed into a fixed parameter. A few functions had a first integer parameter (a count of the remaining parameters). In one

| Implementation    | Context switch times |
|-------------------|----------------------|
| i386 assembler    | 0.059 $\mu$ s        |
| SVR4 system calls | 6.025 $\mu$ s        |

Table 1: *Raw context switch times*

case (`sr_cat`), the loops extracting the parameters from the variable argument list had to be changed to be initialized with the newly introduced fixed parameter.

## 3 Verification methods

SR itself provides a basic and an extended verification suite for the whole system; also a small basic test for the context switching primitives.

The basic suite should be run to test an installation; the context switch tests and the extended suite are used to verify a new porting effort.[4]

### 3.1 Context Switch Primitives

The context switch primitives can be independently tested by running `make` in the subdirectory `csw/` of the distribution; this builds and runs the `cstest` program, which implements a small multithreaded program and checks for detection of stack overflows, stack underflows, correct context switching etc.

### 3.2 Overall System

When the context switch primitives seem to work individually, they — and the building system used to build SR, and the `sr` compiler, linker, etc. need also to be tested.

A basic verification suite is in the `vsuite/` subdirectory of the distribution; it can be extended with more tests from a separate source archive `vs.tar.Z`. It is run by calling the driver script `srv/srv`, which provides normal and verbose modes, as well as using the installed `vs.` the freshly compiled SR system. The only test that is expected to fail is the `srgrind` source code formatter — it needs the `vgrind` program as a backend.

## 4 Performance evaluation

SR comes with two performance evaluation packages. The first, for the context switching primitives, is in the `csw/` subdirectory of the source distribution; after `make csloop` you can start `./csloop N` where `N` is the number of seconds the test will run approximately.

Tests of the language primitives used for multithreading are in the `vsuite/timings/` subdirectory of the source tree enhanced with the verification suite. They are run by three shell scripts to compile them, run them, and summarize the results in a table.

## 5 Establishing a baseline

There are two extremes possible when implementing the context switch primitives needed for SR: implementing each CPU manually in assembler code (what the SR project does normally) and using the SVR4-style `getcontext()` and `setcontext()` functions which operate on `struct ucontext`; these are provided as experimental code in the file `csw/svr4.c` of the SR distribution.

| Test description                         | i386 ASM     | SVR4 s.c.     |
|------------------------------------------|--------------|---------------|
| loop control overhead                    | 0.01 $\mu$ s | 0.01 $\mu$ s  |
| local call, optimised                    | 0.07 $\mu$ s | 0.07 $\mu$ s  |
| interresource call, no new process       | 1.45 $\mu$ s | 1.39 $\mu$ s  |
| interresource call, new process          | 2.95 $\mu$ s | 22.20 $\mu$ s |
| process create/destroy                   | 2.46 $\mu$ s | 26.14 $\mu$ s |
| semaphore P only                         | 0.07 $\mu$ s | 0.07 $\mu$ s  |
| semaphore V only                         | 0.05 $\mu$ s | 0.05 $\mu$ s  |
| semaphore pair                           | 0.11 $\mu$ s | 0.11 $\mu$ s  |
| semaphore requiring context switch       | 0.39 $\mu$ s | 9.09 $\mu$ s  |
| asynchronous send/receive                | 1.71 $\mu$ s | 1.63 $\mu$ s  |
| message passing requiring context switch | 1.90 $\mu$ s | 14.50 $\mu$ s |
| rendezvous                               | 2.65 $\mu$ s | 27.05 $\mu$ s |

Table 2: *Run time system performance. The median times reported by the SR script `vsuite/timings/report.sh` are reported.*

The first tests were done by using the provided i386 assembler context switch routines. After verifying correctness and noting the times (see tables 5 and 5), the same was done using the SVR4 module instead of the assembler module.

All tests were done on a 500 MHz Pentium III machine with 16+16 kB of primary cache and 512 kB of secondary cache, and 128 MB of main memory, running NetBSD-2.0.BETA as of end of June 2004.

The table shows a factor-of-about-ten performance hit for the operations that require context switches; note, however, that the absolute values for all such operations are still smaller than 30  $\mu$ s on 500 MHz machine and will likely not be noticable if a parallelized program is run on a LAN-coupled cluster: on the switched LAN connected to the test machine, the time for an ICMP echo request to return is about 250  $\mu$ s.

## 6 Possible improvements using NetBSD library calls

While using the system calls `getcontext` and `setcontext`, as the `svr4` module does, should not unduly penalize an application distributed across a LAN, it might be noticable with local applications.

However, we should be able to do better than the `svr4` module without writing our own assembler modules, as NetBSD 2.0 (and up) contains its own set of them for the benefit of its native Posix threads library (`libpthread`), which does lots of context switches within a kernel provided light weight process ([5]). The primitives provided to `libpthread` by its machine dependent part are the two functions `_getcontext_u` and `_setcontext_u` with similar signatures to `getcontext` and `setcontext`.

There are a few difficulties that arise while pursuing this.

First, on one architecture (i386) `_setcontext_u` and `_getcontext_u` are implemented by calling through a function pointer which is initialized depending on the FPU / CPU extension mode available on the particular CPU used (on i386, 8087-mode vs. XMM). from this. On this architecture, `_setcontext_u` and `_getcontext_u` are defined as macros in a private header file not installed. The developer in charge of the code has indicated that he might implement public wrappers; until then, we'd have to check all available NetBSD architectures and copy the relevant files.

Second, there is no context initializing function at the same level as `_setcontext_u` and `_getcontext_u`. `makecontext` looks like it would be good enough but this has to

be analyzed further.

## 7 Work items left to do

### 7.1 Building a package for pkgsrc

To ease installation, a prototype package for the NetBSD package system has been built. It needs a bit of refinement, though, but will be available soon. (As the NetBSD package system is available for more operating systems than NetBSD, a bit more work is needed.)

### 7.2 Implementing and testing multithreaded SR

SR can be compiled in a mode where it will make use of multiple threads provided by the underlying OS, so that it can use more than one CPU of a single machine. This has not been implemented yet for NetBSD, but should be.
